

ICS Spring 2018

Lab Session 5

Agenda

- Quiz 1 recap
- Recursion
- Github
- Pickling(Serialization)
- OOP
- In-class exercises

Quiz 1 recap

Quiz 1, Black hole problem

Convert between str, int and list:
str(), int(), join()

```
str(123) '123'  
int('0123') 123  
list('123') ['1', '2', '3']  
# wrong: '123'.split()  
''.join(['1', '2', '3']) '123'
```

Quiz 1, Black hole problem

Convert between str, int and list:
str(), int(), join()

Sorting:
sort(), sorted()

```
str(123) '123'  
int('0123') 123  
list('123') ['1', '2', '3']  
# wrong: '123'.split()  
''.join(['1', '2', '3']) '123'
```

```
# Sorting:  
l = ['4', '2', '1', '3'] ✓  
l.sort() # wrong: new_l = l.sort() ✓  
sorted(l) ['1', '2', '3', '4']  
sorted('4213') ['1', '2', '3', '4']
```

Quiz 1, Black hole problem

Convert between str, int and list:
str(), int(), join()

```
str(123) '123'  
int('0123') 123  
list('123') ['1', '2', '3']  
# wrong: '123'.split()  
''.join(['1', '2', '3']) '123'
```

Sorting:
sort(), sorted()

```
# Sorting:  
l = ['4', '2', '1', '3'] ✓  
l.sort() # wrong: new_l = l.sort() ✓  
sorted(l) ['1', '2', '3', '4']  
sorted('4213') ['1', '2', '3', '4']
```

Reversing:
sort(reverse=True),
sorted(reverse=True),
reverse(),
slicing[::-1]

```
# Reversing:  
l = [1, 2, 3, 4, 5] ✓  
sorted(l, reverse=True) [5, 4, 3, 2, 1]  
l.sort(reverse=True) ✓  
l.reverse() ✓  
l[::-1] [5, 4, 3, 2, 1]  
( '123' )[::-1] '321'
```

Recursion

Recursion

- Concept: A recursive function is a function that calls itself.
- This is a recursive function which runs forever
 - (unless you interrupt with Ctrl+C).

```
def main():  
    message()  
  
def message():  
    print("This is a recursive function.")  
    message()  
  
main()
```

Recursion

- Similar to a loop, a recursive function can be controlled by some decision structure.

```
def main():  
    message(5)  
  
def message(times):  
    if times > 0:  
        print("This is a recursive function.")  
        message(times - 1)  
  
main()
```

Recursion Examples

- Fibonacci Series:

```
def fib(n):  
    if n == 0:  
        return 0  
    elif n == 1:  
        return 1  
    else:  
        return fib(n - 1) + fib(n - 2)
```

Recursion Examples

- Mergesort:

```
def merge_sort(m):  
    print(m)  
  
    if len(m) <= 1:  
        return m  
  
    middle = len(m) // 2  
    left = m[:middle]  
    right = m[middle:]  
  
    left = merge_sort(left)  
    right = merge_sort(right)  
    return merge(left, right)
```

Comprehension

```
def powerset_comb(l):  
    pset = []  
    total_items = len(l)  
    for i in range(2 ** total_items):  
        subset = []  
        code = bin(i).split('b')[-1]  
        code = code[::-1]  
        for j in range(len(code)):  
            if code[j] == '1':  
                subset.append(l[j])  
        pset.append(subset)  
    return pset
```

```
def powerset_comb_list_comprehension(l):  
    pset = []  
    total_items = len(l)  
    for i in range(2 ** total_items):  
        code = bin(i).split('b')[-1]  
        code = code[::-1]  
        subset = [l[j] for j in range(len(code)) if code[j] == '1']  
        pset.append(subset)  
    return pset
```

Recursive Powerset with List Comprehension

```
def powerset_recursion(l):  
    if not l:  
        return [[]]  
    subset = []  
    for x in powerset_recursion(l[1:]):  
        subset.append([l[0]] + x)  
    return powerset_recursion(l[1:]) + subset
```

Use debugger to step into the code!

- Set breakpoint
- Execute/continue
- Print variables....

Recursive Powerset with List Comprehension

```
def powerset_recursion(l):  
    if not l:  
        return [[]]  
    subset = []  
    for x in powerset_recursion(l[1:]):  
        subset.append([l[0]] + x)  
    return powerset_recursion(l[1:]) + subset
```

```
def powerset_recursion_comp(l):  
    # Base case: the empty set  
    if not l:  
        return [[]]  
    # The recursive relation  
    # Do a powerset call for l[1:]  
    # Add lists of all combinations of the 1st element (l[0]) with other elements' powersets  
    return powerset_recursion_comp(l[1:]) + [[l[0]] + x for x in powerset_recursion_comp(l[1:])]
```

Recursion Exercise

Time to work on Problem 1 in today's in-class exercise!

Github

Some materials gathered from Github campus advisors

Git is a version control system

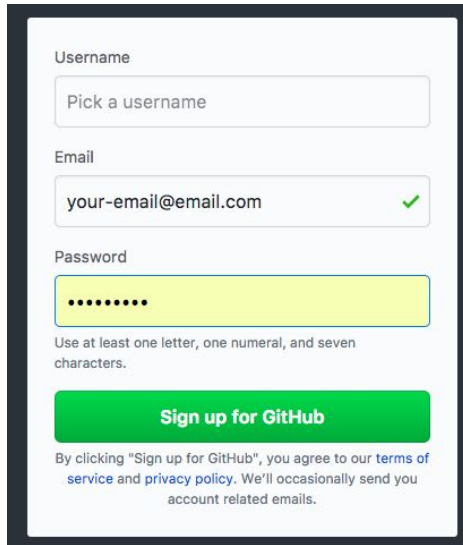

Track your changes and progress overtime.

Go back to previous version when desired.

Register github & install Git bash

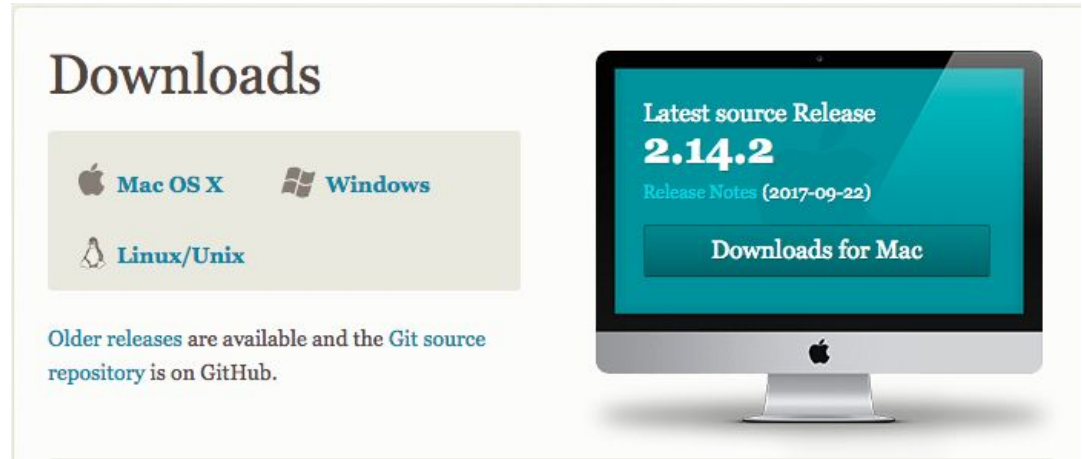

Sign up: <https://github.com/>

The image shows the GitHub sign-up form. It has a white background with a dark border. The form contains the following elements:

- Username:** A text input field with the placeholder text "Pick a username".
- Email:** A text input field with the placeholder text "your-email@email.com" and a green checkmark icon on the right.
- Password:** A text input field with a yellow background and a series of dots for the password.
- Instructions:** Below the password field, it says "Use at least one letter, one numeral, and seven characters."
- Sign up button:** A green button with the text "Sign up for GitHub".
- Disclaimer:** Below the button, it says "By clicking 'Sign up for GitHub', you agree to our [terms of service](#) and [privacy policy](#). We'll occasionally send you account related emails."

Install Git bash : <https://git-scm.com/downloads>

Github: the framework

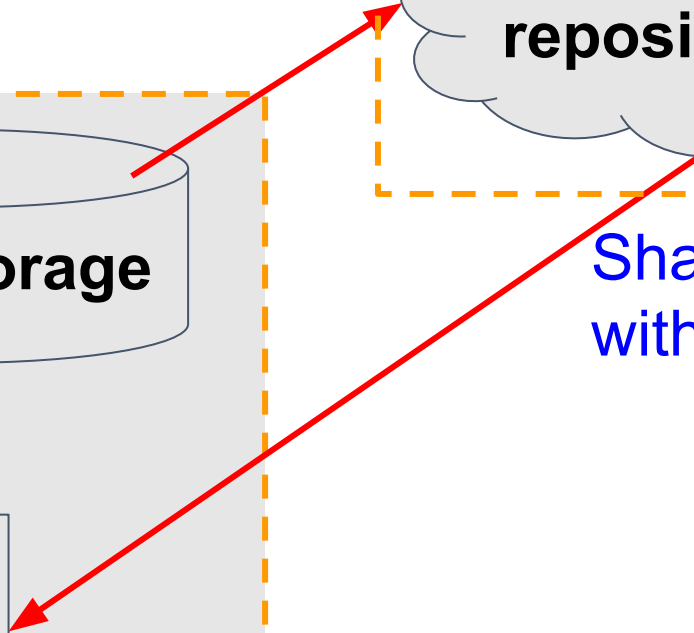

On your laptop

The web

Share and collaborate
with others

Github: the framework

On your laptop

How does the version control work exactly?

Git takes snapshots

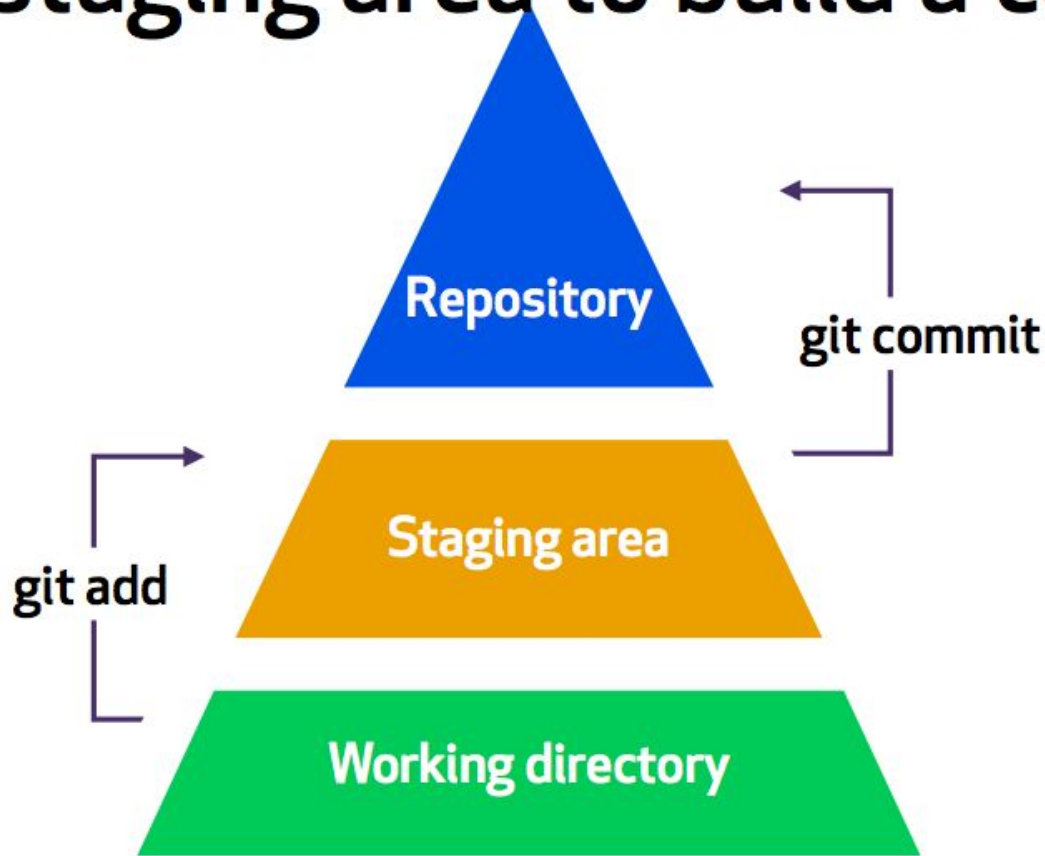

Save snapshots to your history to retrace your steps.

Also keeps others up-to-date with your latest work.

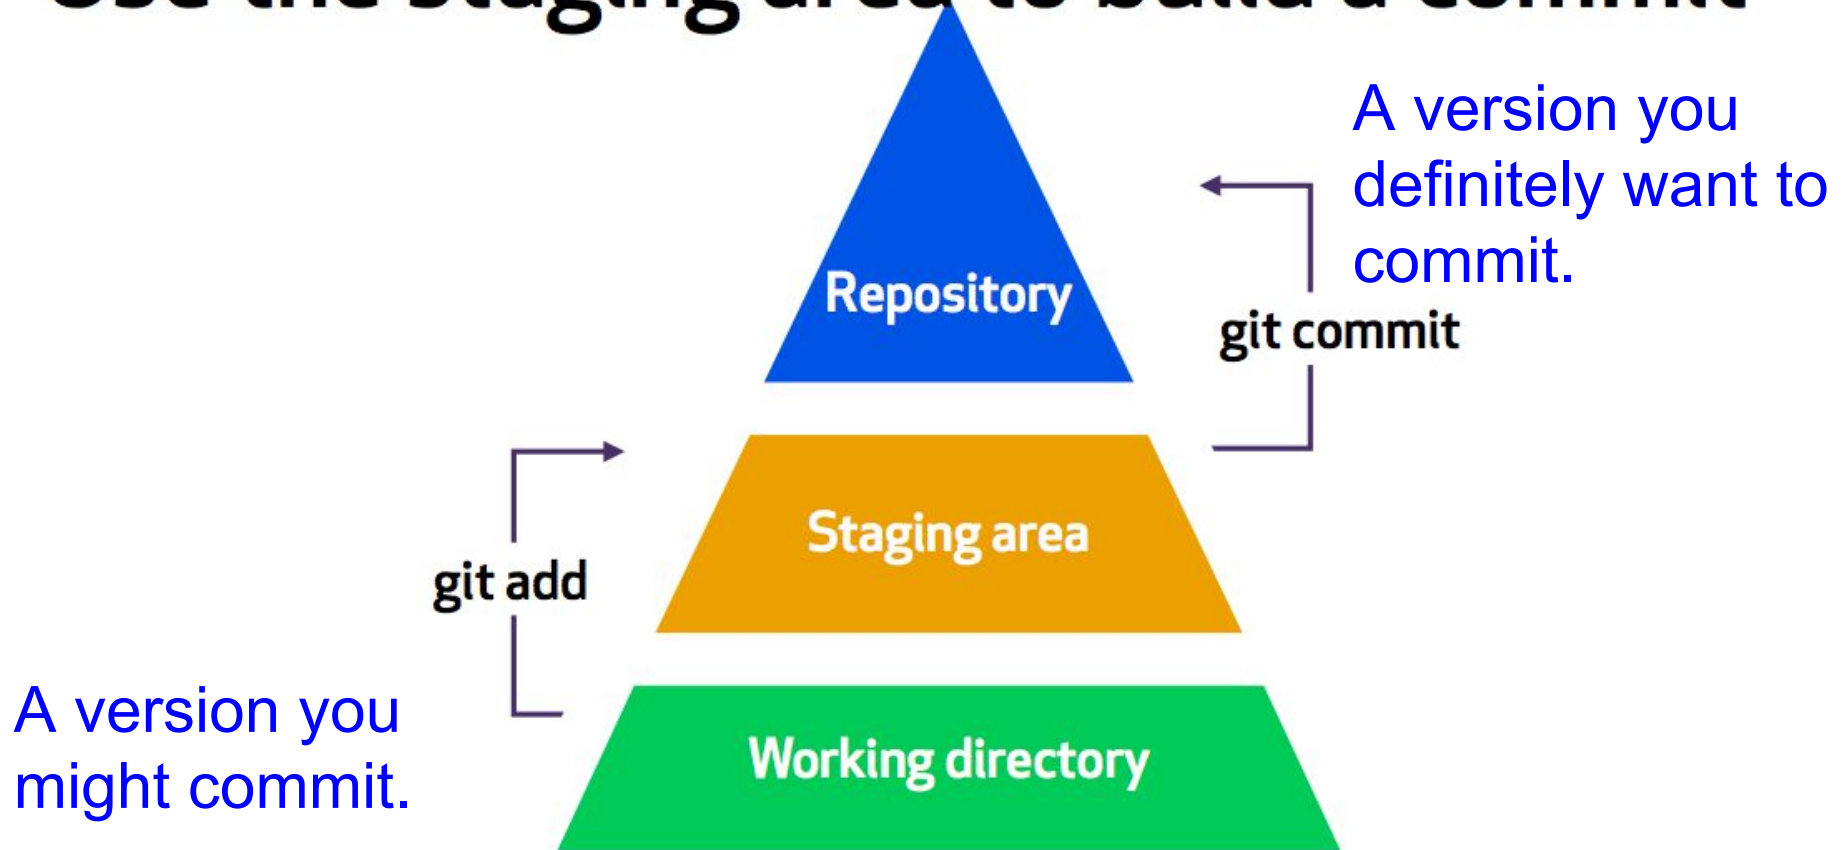

snapshot = “commit” in git vocabulary

Use the staging area to build a commit

Use the staging area to build a commit

Use Case: Track of your ICS codes

Suppose you have a ICS folder with one python file you want to keep track of changes:

Directory: desktop/git_demo

Original version : Downloaded from NYU class as code template.

1.Create a repository: Tell git you want to track this folder

```
cd desktop/git_demo  
git init
```

```
ls -la # check files
```

Note: Right now, nothing is tracked by git yet

2. Make initial commit

```
git add xxxx.py  
git commit -m 'initial commit'  
git log # show commit history
```

Why “add”?

Store the new version in staging area.

But you can still make further changes before commit

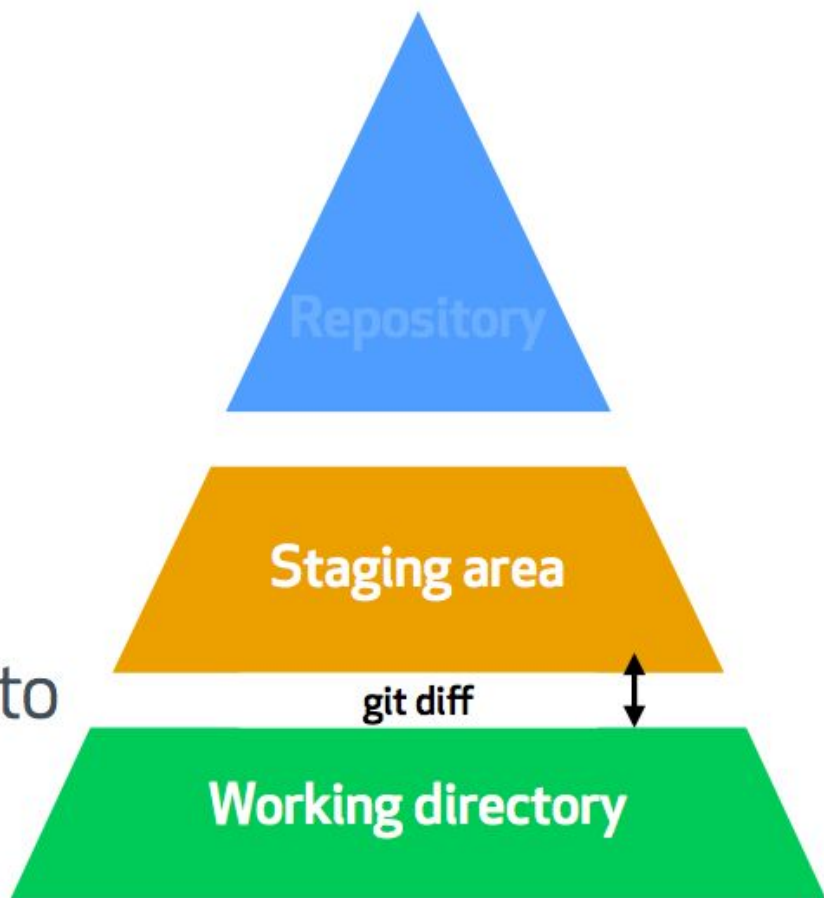

3. Work on the code, then check differences

```
git diff
```

```
git diff --staged
```

git diff

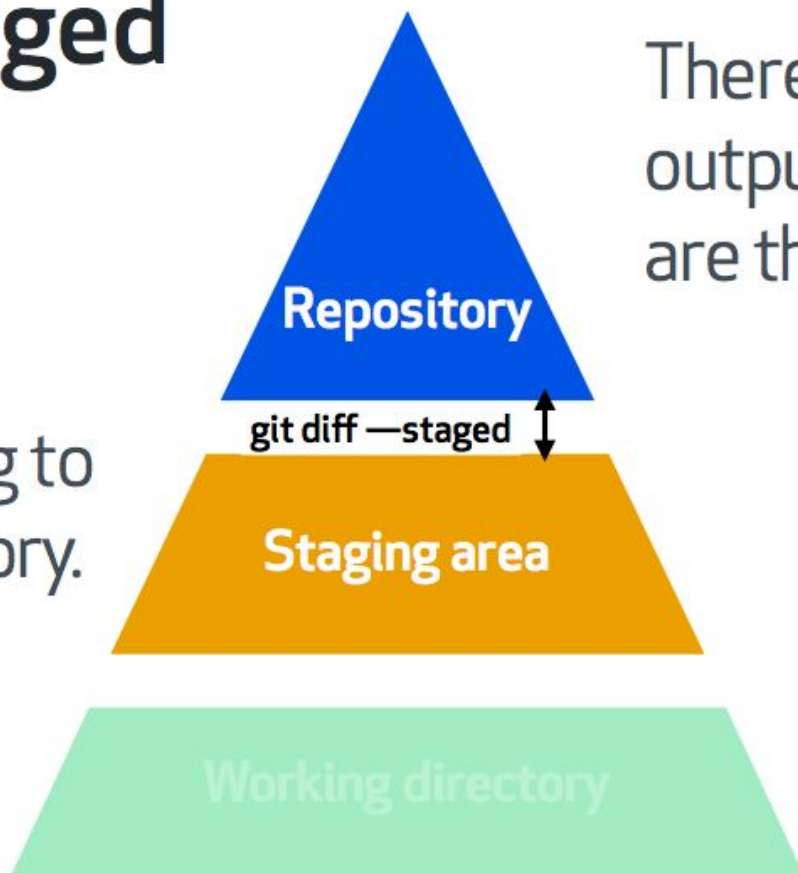

Compares staging to
working directory.

There's no
output if they
are the same.

git diff --staged

Compares staging to repository directory.

There's no output if they are the same.

4. Commit your changes

```
git add xxxxx.py
```

```
git commit -m 'xxxx version 1'
```

```
git log
```

After git log, you should see 2 commits, with name, author and time.

5. Go back to initial (or any previous) commit

- If you just want take a look of a past version....
- ... and then go back to most recent commit.

```
git checkout <commit name>
```

```
git checkout master
```

- If you want to make new changes that are different than most recent commit: (we will discuss that next week)
 1. make a branch
 2. discard all commit since this previous commit

Pickles & Object Serialization

Pickling

- We can directly work with binary files with the pickle module
- To use: import the pickle module, use the appropriate file mode
 - 'r' -> 'rb' (read binary)
 - 'w' -> 'wb'
- `pickle.dump()`
 - Writes an object directly to file as its native data type
 - (***not*** a string!)
- `pickle.load()`
 - Reads the first available binary object in the file and returns it

Pickling Analysis

Serialize the data:

```
import pickle
capitals = {"Illinois": "Springfield",
            "California": "Sacramento",
            "New York": "Albany"}
output_file = open("capitals.dat", "wb")
pickle.dump(capitals, output_file)
output_file.close()
```

Pickling Analysis

Load the serialized data

```
import pickle
input_file = open("capitals.dat", "rb")
caps = pickle.load(input_file)
print(caps)
```

Output:

```
{'California': 'Sacramento', 'Illinois': 'Springfield', 'New York': 'Albany'}
```

Object Oriented Programming (OOP)

Elegance

The programmer's conundrum:

Pick any two!

Convenience

Clarity

Example of a Class

the `__init__` method
-- define the variables

Mutate method(Setter)

Coding style (again)!

Access method(Getter)

Program 10-1

(Coin class, not a complete program)

```
1 import random
2
3 # The Coin class simulates a coin that can
4 # be flipped.
5
6 class Coin:
7
8     # The __init__ method initializes the
9     # sideup data attribute with 'Heads'.
10
11     def __init__(self):
12         self.sideup = 'Heads'
13
14     # The toss method generates a random number
15     # in the range of 0 through 1. If the number
16     # is 0, then sideup is set to 'Heads'.
17     # Otherwise, sideup is set to 'Tails'.
18
19     def toss(self):
20         if random.randint(0, 1) == 0:
21             self.sideup = 'Heads'
22         else:
23             self.sideup = 'Tails'
24
25     # The get_sideup method returns the value
26     # referenced by sideup.
27
28     def get_sideup(self):
29         return self.sideup
```

Everything in Python is Object!

- Everything is actually a class instance in python
 - And almost ***everything*** has attributes and methods
- Anything which can be used as a value (int, str, float, functions, modules, etc) are implemented as objects.

OOP Exercises

Now, please go ahead working on Problems 2 & 3 in today's in-class exercise!
